# Mersey River Flow Study

## Introduction

This study examines the Mersey River at Liena streamflows to compare the pre- and post-Hydro development of the Parangana Dam. This report is intended to complement the Mersey River Flow Estimation Study prepared by Crispin Smythe from the HEC. Data used was extracted from Site 60 (Mersey at Liena) using Hydrol (a software package used to manage and analyse hydrological time series data). Hellyer River at Guilford, Site 61 was also studied as a control. Table 1 defines the terms pre- and post-dam data used in this analysis.

Table 1 Site and data time periods

Site	Pre-Dam data	Post-Dam data
Mersey at Liena (60)	1/8/1950 - 1/1/1967	1/1/1971 - 30/6/1997
Hellyer at Guilford (61)	1/2/1922 - 1/1/1967	1/1/1971 - 30/6/1997

Data variables examined include monthly minimum, maximum, average and median flows (cumecs). Each month was examined individually to explore the effects of Parangana Dam. Data were analysed using simple t-tests assuming independent samples and unequal variances. Genstat 5 and Minitab 11 were used for the afore mentioned analysis.

## Results

Simple plots of the mean and median data shows significantly greater river flows at Liena pre-dam compared to the post-dam flow for all months (Figure 1). This difference is approximately an order of magnitude (i.e. ten times the flow pre-dam).

The summary of all the data (Appendix 1) also indicates there is a greater flow pre-dam than post-dam for all months. There was only one statistical test (Appendix 2) that showed there was no significant difference ( $p < 0.05$ ) between pre- and post-dam flows. This occurred in January when comparing the maximum flows for that month. Every other test for all variables showed a significantly greater flow pre-dam than post-dam.

Analysis of the Hellyer River at Guilford site indicated that there were significantly ( $p < 0.05$ ) greater average and maximum flows for the month of November pre-dam period than post-dam period. Outside of these results no other significant differences were found to exist between the pre- and post-dam periods for monthly flows.

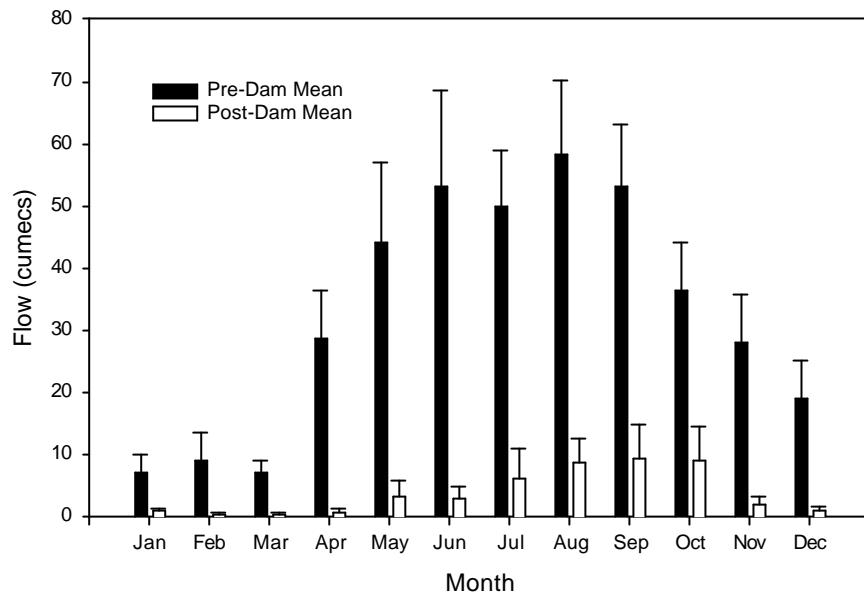

## Discussion

It is clear from the graphs alone that there has been a significant reduction in the flow of the Mersey River at Liena. This reduction can be directly attributed to the Hydro development of the Parangana Dam, especially as the monthly flows of the Hellyer River at Guilford are on the whole not significantly different in the pre- and post-time periods.

While the flows are significantly different the annual trends of the pre- and post- dam monthly flows are similar although the summer (Dec - Mar) flows are somewhat reduced. Post- dam monthly flows are highly skewed in comparison with pre-dam flows (Figure 1). That is, the change in normal flow regime down stream of Parangana has changed significantly more than the mean statistics show. Figure 1 also shows the significance of April floods in terms of breaking the low flow conditions in the Mersey River.
